

# 5 THE SKELETAL SYSTEM

The skeleton is constructed of two of the most supportive tissues found in the human body—cartilage and bone. Besides supporting and protecting the body as an internal framework, the skeleton provides a system of levers that the skeletal muscles use to move the body. In addition, the bones provide a storage depot for substances such as lipids and calcium, and blood cell formation goes on within the red marrow cavities of bones.

The skeleton consists of bones connected at joints, or articulations, and is subdivided into two divisions. The axial skeleton includes those bones that lie around the body's center of gravity. The appendicular skeleton includes the bones of the limbs and girdles.

Topics for student review include structure and function of long bones, location and naming of specific bones in the skeleton, fracture types, and a classification of joint types in the body.

*Anatomy & Physiology* Tracey Greenwood, Lissa Bainbridge-Smith, Kent Pryor, Richard Allan, 2013-06-15 *Anatomy and Physiology* explores the essentials of human structure and function through engaging generously illustrated activities. Much of the content in the first edition has been revised to include larger diagrams, more photographs and greater depth of coverage in key areas. Sound biological principles are emphasised throughout and key interactions between body systems are indicated using annotated introductory figures. Using key examples, students are encouraged to explore each body system within the contexts of disease, medicine and technology, aging and exercise. The result is a rounded exploration of the functioning human. Back cover

Pittman,2016-08-18 This presentation describes various aspects of the regulation of tissue oxygenation including the roles of the circulatory system respiratory system and blood the carrier of oxygen within these components of the cardiorespiratory system The respiratory system takes oxygen from the atmosphere and transports it by diffusion from the air in the alveoli to the blood flowing through the pulmonary capillaries The cardiovascular system then moves the oxygenated blood from the heart to the

microcirculation of the various organs by convection where oxygen is released from hemoglobin in the red blood cells and moves to the parenchymal cells of each tissue by diffusion Oxygen that has diffused into cells is then utilized in the mitochondria to produce adenosine triphosphate ATP the energy currency of all cells The mitochondria are able to produce ATP until the oxygen tension or PO<sub>2</sub> on the cell surface falls to a critical level of about 4 5 mm Hg Thus in order to meet the energetic needs of cells it is important to maintain a continuous supply of oxygen to the mitochondria at or above the critical PO<sub>2</sub> In order to accomplish this desired outcome the cardiorespiratory system including the blood must be capable of regulation to ensure survival of all tissues under a wide range of circumstances The purpose of this presentation is to provide basic information about the operation and regulation of the cardiovascular and respiratory systems as well as the properties of the blood and parenchymal cells so that a fundamental understanding of the regulation of tissue oxygenation is achieved
